Recall

- Labs start Thursday, Jan 21
  - Refer to the course web page for instructions, handouts, and many links to read
  - Do these, prior to go to the lab
- Use all resources available to you
  - Before it becomes too late!
  - What resources?
    - The course web page and its many hyperlinks!
    - Office Hours: W 4:00-5:45 BA432
    - The CS Help Center
    - Email archinaei@cs.toronto.edu

Review

- So far
  - Recap of basic Python
    - refer to ramp_up slides in the course web page
  - Introduction to object oriented design
  - In particular, defining new compound data types – classes
  - Examples: Class Rectangle, Class Point
- Today
  - Special methods
  - Manage attributes
  - Introduction to composition and inheritance

Key terms

- Class: (abstract/advanced/compound) data type
  - It models a thing or concept (let’s call it object), based on its common (or important) attributes and actions in a specific project
  - In other words, it bundles together attributes and methods that are relevant to each instance of those objects
- In OO world, objects are often active agents
  - In other words, actions are invoked on objects
  - E.g., you invoke an action on your phone to dial a number
  - E.g., you invoke an action on your alarm to wake you up
  - E.g., you invoke an action on your fridge to get ice

Design roadmap--Step 1

- Before Start!
  - Read the project specification carefully
  - In the specification:
    - frequent nouns may be good candidates for classes
    - properties of such nouns may be good candidates for attributes
    - actions of such nouns may be good candidates for methods
    - Keep in mind, that there are some special methods that are relevant to many classes

Point class(revisited)

- Specification:
  - In two dimensions, a point is two numbers (coordinates) that are treated collectively as a single object. Points are often written in parentheses with a comma separating the coordinates. For example, (0, 0) represents the origin, and (x, y) represents the point x units to the right and y units up from the origin. Some of the typical operations that one associates with points might be calculating the distance of a point from the origin, or from another point, or finding a midpoint of two points, or asking if a point falls within a given rectangle or circle.
Designing Classes

Point class(revisited)

 Specification:

In two dimensions, a point is two numbers (coordinates) that are treated collectively as a single object. Points are often written in parentheses with a comma separating the coordinates. For example, \((0, 0)\) represents the origin, and \((x, y)\) represents the point \(x\) units to the right and \(y\) units up from the origin. Some of the typical operations that one associates with points might be calculating the distance of a point from the origin, or from another point, or finding a midpoint of two points, or asking if a point falls within a given rectangle or circle.

Designing Classes

Point class(revisited)

 Specification:

In two dimensions, a point is two numbers (coordinates) that are treated collectively as a single object. Points are often written in parentheses with a comma separating the coordinates. For example, \((0, 0)\) represents the origin, and \((x, y)\) represents the point \(x\) units to the right and \(y\) units up from the origin. Some of the typical operations that one associates with points might be calculating the distance of a point from the origin, or from another point, or finding a midpoint of two points, or asking if a point falls within a given rectangle or circle.

Designing Classes

Point class(revisited)

 Specification:

In two dimensions, a point is two numbers (coordinates) that are treated collectively as a single object. Points are often written in parentheses with a comma separating the coordinates. For example, \((0, 0)\) represents the origin, and \((x, y)\) represents the point \(x\) units to the right and \(y\) units up from the origin. Some of the typical operations that one associates with points might be calculating the distance of a point from the origin, or from another point, or finding a midpoint of two points, or asking if a point falls within a given rectangle or circle.

Designing Classes

Design roadmap--Step 2

 Specification:

Now, we can define a class API:

1. choose a class name and write a brief description in the class docstring
2. write some examples of client code that uses your class
3. decide what services your class should provide as public methods, for each method declare an API (examples, type contract, header, description)
   refer to CSC108 function design recipe
4. decide which attributes your class should provide without calling a method, list them in the class docstring

Designing Classes

Design roadmap--Step 3

 Specification:

Then, implement the class:

1. body of special methods, 
   \_init\_, \_eq\_, \_str\_

2. body of other methods
   \texttt{eg.} \texttt{distance}

3. testing (more on this later)

Designing Classes

Let's do it in PyCharm …
**Rectangle class**

A rectangle can be defined in many different ways. Here, assume a rectangle is defined by its top-left coordinates as well as its width and height. A rectangle is usually represented by a quadruple \((x, y, w, h)\) where \(x\) and \(y\) represent the top-left coordinate, \(w\) represents the width, and \(h\) represents the height. For example, \((10, 20, 300, 400)\) represents a rectangle that its top-left coordinate is located at point \((10, 20)\), its width is 300 and its height is 400. Some of the typical operations that one associates with rectangles might be translating the rectangle to the right, left, up, and down, or asking if two rectangles are conceptually equal, which means have same coordinate and size, or asking if a rectangle falls within another rectangle, etc.

**Rational class**

Rational numbers are ratios of two integers \(p/q\), where \(p\) is called the numerator and \(q\) is called the denominator. The denominator \(q\) is non-zero. Operations on rationals include addition, multiplication, and comparisons:

\[
\langle \rangle < \leq > \geq =
\]

Recall: design roadmap

- **Step 1:** Read the project specification carefully

Rational numbers are ratios of two integers \(p/q\), where \(p\) is called the numerator and \(q\) is called the denominator. The denominator \(q\) is non-zero. Operations on rationals include addition, multiplication, and comparisons:

\[
\langle \rangle < \leq > \geq =
\]

Note: Python provides special methods:

- `__ne__`  `__lt__`  `__le__`  `__gt__`  `__ge__`  `__eq__`

Other special methods: `__init__`  `__str__`  `__add__`  `__mul__` …

Recall: design roadmap

- **Step 2:** Define a class API:
  1. choose a class name and write a brief description in the class docstring
  2. write some examples of client code that uses your class
  3. decide what services your class should provide as public methods, for each method declare an API (examples, type contract, header, description)
    - refer to CSC108 function design recipe
  4. decide which attributes your class should provide without calling a method, list them in the class docstring

API: class definition & constructor

```python
class Rational:
    A rational number

    def __init__(self, num, denom=1):
        Create new Rational self with numerator num and
denominator denom --- denom must not be 0.
        @type self: Rational
        @type num: int
        @type denom: int
        @rtype: None

        pass
```

Designing Classes I-18
Designing Classes

API: other methods (==)

```python
def __eq__(self, other):
    """Return whether Rational self is equivalent to other."
    @type self: Rational
    @type other: Rational | Any
    @rtype: bool
    >>> r1 = Rational(3, 5)
    >>> r2 = Rational(6, 10)
    >>> r3 = Rational(4, 7)
    >>> r1 == r2
    True
    >>> r1.__eq__(r3)
    False
    pass
```

API: other methods (str())

```python
def __str__(self):
    """Return a user-friendly string representation of Rational self."
    @type self: Rational
    @rtype: str
    >>> print(Rational(3, 5))
    3 / 5
    pass
```

API: other methods (<)

```python
def __lt__(self, other):
    """Return whether Rational self is less than other."
    @type self: Rational
    @type other: Rational | Any
    @rtype: bool
    >>> Rational(3, 5).__lt__(Rational(4, 7))
    False
    >>> Rational(3, 5).__lt__(Rational(3, 7))
    True
    pass
```

API: other methods (*)

```python
def __mul__(self, other):
    """Return the product of Rational self and Rational other."
    @type self: Rational
    @type other: Rational
    @rtype: Rational
    >>> print(Rational(3, 5).__mul__(Rational(4, 7)))
    12 / 35
    pass
```

API: other methods (+)

```python
def __add__(self, other):
    """Return the sum of Rational self and Rational other."
    @type self: Rational
    @type other: Rational
    @rtype: Rational
    >>> print(Rational(3, 5).__add__(Rational(4, 7)))
    41 / 35
    pass
```

... design roadmap

- Continue to develop API for all other methods
- Then, Step 3: Develop the implementation
imp: class definition & constructor

class Rational:
    A rational number
    
    def __init__(self, num, denom=1):
        Create new Rational self with numerator num and

                        self.denom * other.denom)

imp: other methods (+)

def __add__(self, other):
    
    # Return the sum of Rational self and Rational other.
    @type self: Rational
    @type other: Rational
    @rtype: Rational
    
    >>> print(Rational(3, 5).__add__(Rational(4, 7)))
    43 / 35
    >>> return Rational(self.num + other.denom +
                        other.num + self.denom,
                        self.denom + other.denom)
What if the denominator is 0?

Getters, setters and properties

def _get_num(self):
    # Return numerator num.
    # @type self: Rational
    # @type: int
    # >>> Rational(3, 4)._get_num()
    # 3
    return self._num

Getters, setters and properties

def _set_num(self, num):
    # Set numerator of Rational self to num.
    # @type self: Rational
    # @type num: int
    # @rtype: None
    self._num = int(num)
    num = property(_get_num, _set_num)

Getters, setters and properties

def _get_denom(self):
    # Return denominator of Rational self.
    # @type self: Rational
    # @type: int
    # >>> Rational(3, 4)._get_denom()
    # 4
    # @rtype: None
    return self._denom

Getters, setters and properties

def _set_denom(self, denom):
    # Set denominator of Rational self to denom.
    # @type self: Rational
    # @type denom: int
    # @rtype: None
    if denom == 0:
        raise Exception("Zero denominator!")
    else:
        self._denom = int(denom)
    denom = property(_get_denom, _set_denom)

Introduction to OOP features

- Composition and Inheritance
  - A rectangle has some vertices (points)
  - A triangle has some vertices (points)
  - A triangle is a shape
  - A rectangle is a shape
- has_a vs is_a relationship
- a shape has a perimeter
  - A rectangle can inherit the perimeter from a shape
  - A triangle too
- a shape has an area
  - Can be area of a rectangle or triangle abstracted to the shape level!
