With a few exceptions, these slides were developed by **David Silver** following the notation and development in:

Reinforcement Learning: An Introduction
Sutton & Barto, (Draft 2nd edition)

Thank you to David for sharing his slides.

NOTATION WARNING:

The notation in Sutton & Barto has changed from the 1st to 2nd edition of their book. As you read papers, you'll also see that notation in the RL and MDP communities varies.

Different Classes Planning Problems

dynamics: deterministic, nondeterministic, probabilistic

observability: full, partial, none

horizon: finite, infinite

objective requirement: satisfying, optimizing

. . .

- classical planning
- conditional planning with full observability (FOND)
- conditional planning with partial observability (POND)
- conformant planning
- markov decision processes (MDP)
- partial observable MDP (POMDP)
- preference-based/over-subscription planning

1 Markov Processes

2 Markov Reward Processes

- 3 Markov Decision Processes
- 4 Extensions to MDPs

Introduction

Introduction to MDPs

- Markov decision processes formally describe an environment for reinforcement learning
- Where the environment is *fully observable*
- i.e. The current *state* completely characterises the process
- Almost all RL problems can be formalised as MDPs, e.g.
 - Optimal control primarily deals with continuous MDPs
 - Partially observable problems can be converted into MDPs
 - Bandits are MDPs with one state

Markov Property

"The future is independent of the past given the present"

Definition

A state S_t is *Markov* if and only if

$$\mathbb{P}[S_{t+1} \mid S_t] = \mathbb{P}[S_{t+1} \mid S_1, ..., S_t]$$

- The state captures all relevant information from the history
- Once the state is known, the history may be thrown away
- i.e. The state is a sufficient statistic of the future

State Transition Matrix

For a Markov state s and successor state s', the state transition probability is defined by

$$\mathcal{P}_{ss'} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s\right]$$

State transition matrix \mathcal{P} defines transition probabilities from all states s to all successor states s',

$$\mathcal{P} = from \begin{bmatrix} \mathcal{P}_{11} & \dots & \mathcal{P}_{1n} \\ \vdots & & & \\ \mathcal{P}_{n1} & \dots & \mathcal{P}_{nn} \end{bmatrix}$$

where each row of the matrix sums to 1.

Markov Process

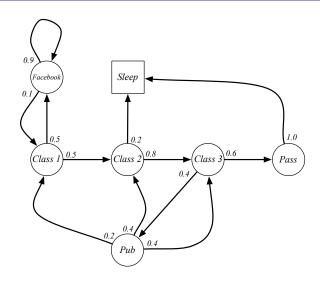

A Markov process is a memoryless random process, i.e. a sequence of random states $S_1, S_2, ...$ with the Markov property.

Definition

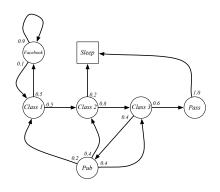

A Markov Process (or Markov Chain) is a tuple $\langle \mathcal{S}, \mathcal{P} \rangle$

- lacksquare \mathcal{S} is a (finite) set of states
- \mathcal{P} is a state transition probability matrix, $\mathcal{P}_{ss'} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s\right]$

Example: Student Markov Chain

Example: Student Markov Chain Episodes

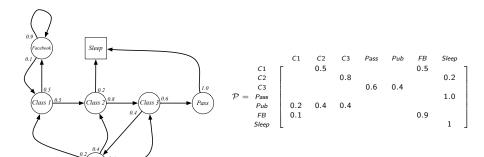

Sample episodes for Student Markov Chain starting from $S_1 = C1$

$$S_1, S_2, ..., S_T$$

- C1 FB FB C1 C2 C3 Pub C1 FB FB FB C1 C2 C3 Pub C2 Sleep

Example: Student Markov Chain Transition Matrix

Markov Reward Process

A Markov reward process is a Markov chain with values.

Definition

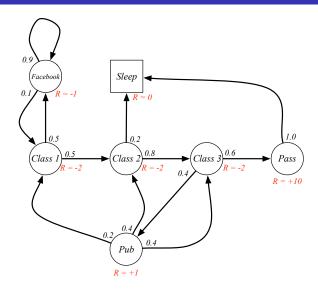

A Markov Reward Process is a tuple $\langle \mathcal{S}, \mathcal{P}, \mathcal{R}, \gamma \rangle$

- lacksquare \mathcal{S} is a finite set of states
- \mathcal{P} is a state transition probability matrix,

$$\mathcal{P}_{ss'} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s\right]$$

- \mathcal{R} is a reward function, $\mathcal{R}_s = \mathbb{E}\left[R_{t+1} \mid S_t = s\right]$
- lacksquare γ is a discount factor, $\gamma \in [0,1]$

Example: Student MRP

Return

Return

Definition

The return G_t is the total discounted reward from time-step t.

$$G_t = R_{t+1} + \gamma R_{t+2} + \dots = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1}$$

- The *discount* $\gamma \in [0,1]$ is the present value of future rewards
- The value of receiving reward R after k+1 time-steps is $\gamma^k R$.
- This values immediate reward above delayed reward.
 - $lue{\gamma}$ close to 0 leads to "myopic" evaluation
 - ullet γ close to 1 leads to "far-sighted" evaluation

Why discount?

Most Markov reward and decision processes are discounted. Why?

- Mathematically convenient to discount rewards
- Avoids infinite returns in cyclic Markov processes
- Uncertainty about the future may not be fully represented
- If the reward is financial, immediate rewards may earn more interest than delayed rewards
- Animal/human behaviour shows preference for immediate reward
- It is sometimes possible to use *undiscounted* Markov reward processes (i.e. $\gamma=1$), e.g. if all sequences terminate.

Value Function

The value function v(s) gives the long-term value of state s

Definition

The state value function v(s) of an MRP is the expected return starting from state s

$$v(s) = \mathbb{E}\left[G_t \mid S_t = s\right]$$

Example: Student MRP Returns

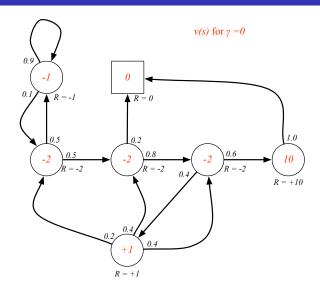

Sample returns for Student MRP: Starting from $S_1 = C1$ with $\gamma = \frac{1}{2}$

$$G_1 = R_2 + \gamma R_3 + \dots + \gamma^{T-2} R_T$$

C1 C2 C3 Pass Sleep
$$v_1 = -2 - 2 * \frac{1}{2} - 2 * \frac{1}{4} + 10 * \frac{1}{8} \\ v_1 = -2 - 1 * \frac{1}{2} - 1 * \frac{1}{4} - 2 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_1 = -2 - 2 * \frac{1}{2} - 2 * \frac{1}{4} + 10 * \frac{1}{8} \\ v_2 = -2 - 1 * \frac{1}{2} - 1 * \frac{1}{4} - 2 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_3 = -3.125 \\ v_1 = -2 - 2 * \frac{1}{2} - 2 * \frac{1}{2} + 1 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_2 = -2 - 2 * \frac{1}{2} - 2 * \frac{1}{2} + 1 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_3 = -3.41 \\ v_4 = -2 - 1 * \frac{1}{2} - 1 * \frac{1}{4} - 2 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_5 = -3.20 \\ v_7 = -2 - 1 * \frac{1}{2} - 1 * \frac{1}{4} - 2 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_7 = -2 - 1 * \frac{1}{2} - 1 * \frac{1}{4} - 2 * \frac{1}{8} - 2 * \frac{1}{16} \\ v_7 = -3.20 \\ v_8 = -3.20 \\ v_8 = -3.41 \\ v_8 = -3.20 \\ v_8 = -3.41 \\ v_8 = -3.41 \\ v_9 = -3.20 \\ v_9 = -3.2$$

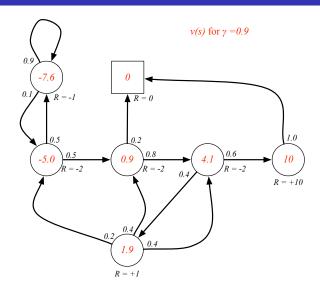

└─Value Function

Example: State-Value Function for Student MRP (2)

└─Value Function

Example: State-Value Function for Student MRP (3)

Bellman Equation for MRPs

The value function can be decomposed into two parts:

- \blacksquare immediate reward R_{t+1}
- discounted value of successor state $\gamma v(S_{t+1})$

$$v(s) = \mathbb{E} [G_t \mid S_t = s]$$

$$= \mathbb{E} [R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \dots \mid S_t = s]$$

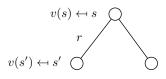

$$= \mathbb{E} [R_{t+1} + \gamma (R_{t+2} + \gamma R_{t+3} + \dots) \mid S_t = s]$$

$$= \mathbb{E} [R_{t+1} + \gamma G_{t+1} \mid S_t = s]$$

$$= \mathbb{E} [R_{t+1} + \gamma v(S_{t+1}) \mid S_t = s]$$

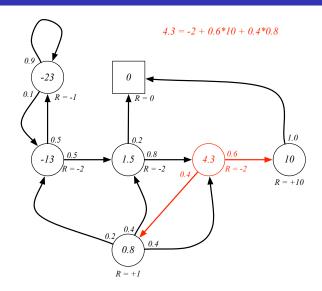

Bellman Equation for MRPs (2)

$$v(s) = \mathbb{E}\left[R_{t+1} + \gamma v(S_{t+1}) \mid S_t = s\right]$$

$$v(s) = \mathcal{R}_s + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'} v(s')$$

Example: Bellman Equation for Student MRP

Bellman Equation in Matrix Form

The Bellman equation can be expressed concisely using matrices,

$$\mathbf{v} = \mathcal{R} + \gamma \mathcal{P} \mathbf{v}$$

where v is a column vector with one entry per state

$$\begin{bmatrix} v(1) \\ \vdots \\ v(n) \end{bmatrix} = \begin{bmatrix} \mathcal{R}_1 \\ \vdots \\ \mathcal{R}_n \end{bmatrix} + \gamma \begin{bmatrix} \mathcal{P}_{11} & \dots & \mathcal{P}_{1n} \\ \vdots & & \\ \mathcal{P}_{11} & \dots & \mathcal{P}_{nn} \end{bmatrix} \begin{bmatrix} v(1) \\ \vdots \\ v(n) \end{bmatrix}$$

Solving the Bellman Equation

- The Bellman equation is a linear equation
- It can be solved directly:

$$v = \mathcal{R} + \gamma \mathcal{P} v$$
$$(I - \gamma \mathcal{P}) v = \mathcal{R}$$
$$v = (I - \gamma \mathcal{P})^{-1} \mathcal{R}$$

- Computational complexity is $O(n^3)$ for n states
- Direct solution only possible for small MRPs
- There are many iterative methods for large MRPs, e.g.
 - Dynamic programming
 - Monte-Carlo evaluation
 - Temporal-Difference learning

Markov Decision Process

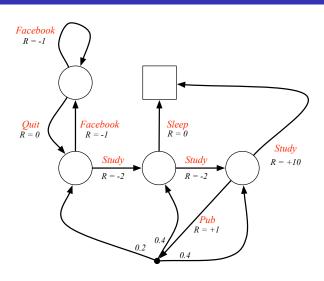

A Markov decision process (MDP) is a Markov reward process with decisions. It is an *environment* in which all states are Markov.

Definition

A Markov Decision Process is a tuple $\langle S, A, P, R, \gamma \rangle$

- lacksquare \mathcal{S} is a finite set of states
- \blacksquare \mathcal{A} is a finite set of actions
- \mathcal{P} is a state transition probability matrix, $\mathcal{P}_{cc'}^{a} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s, A_t = a\right]$
- \mathcal{R} is a reward function, $\mathcal{R}_{s}^{a} = \mathbb{E}\left[R_{t+1} \mid S_{t} = s, A_{t} = a\right]$
- γ is a discount factor $\gamma \in [0,1]$.

Example: Student MDP

Policies (1)

Definition

A policy π is a distribution over actions given states,

$$\pi(a|s) = \mathbb{P}\left[A_t = a \mid S_t = s\right]$$

- A policy fully defines the behaviour of an agent
- MDP policies depend on the current state (not the history)
- i.e. Policies are *stationary* (time-independent), $A_t \sim \pi(\cdot|S_t), \forall t > 0$

└ Policies

Policies (2)

- Given an MDP $\mathcal{M} = \langle \mathcal{S}, \mathcal{A}, \mathcal{P}, \mathcal{R}, \gamma \rangle$ and a policy π
- The state sequence $S_1, S_2, ...$ is a Markov process $\langle \mathcal{S}, \mathcal{P}^\pi \rangle$
- The state and reward sequence $S_1, R_2, S_2, ...$ is a Markov reward process $\langle S, \mathcal{P}^{\pi}, \mathcal{R}^{\pi}, \gamma \rangle$
- where

$$\mathcal{P}^{\pi}_{s,s'} = \sum_{a \in \mathcal{A}} \pi(a|s) \mathcal{P}^{a}_{ss'}$$
 $\mathcal{R}^{\pi}_{s} = \sum_{a \in \mathcal{A}} \pi(a|s) \mathcal{R}^{a}_{s}$

Value Function

Definition

The state-value function $v_{\pi}(s)$ of an MDP is the expected return starting from state s, and then following policy π

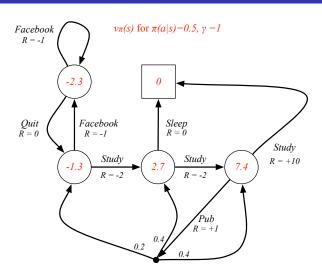

$$v_{\pi}(s) = \mathbb{E}_{\pi}\left[G_t \mid S_t = s\right]$$

Definition

The action-value function $q_{\pi}(s,a)$ is the expected return starting from state s, taking action a, and then following policy π

$$q_{\pi}(s,a) = \mathbb{E}_{\pi}\left[G_t \mid S_t = s, A_t = a\right]$$

Example: State-Value Function for Student MDP

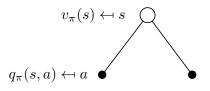

The state-value function can again be decomposed into immediate reward plus discounted value of successor state,

$$v_{\pi}(s) = \mathbb{E}_{\pi} \left[R_{t+1} + \gamma v_{\pi}(S_{t+1}) \mid S_t = s \right]$$

The action-value function can similarly be decomposed,

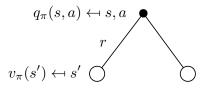

$$q_{\pi}(s, a) = \mathbb{E}_{\pi} \left[R_{t+1} + \gamma q_{\pi}(S_{t+1}, A_{t+1}) \mid S_t = s, A_t = a \right]$$

Bellman Expectation Equation for V^π

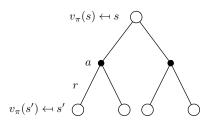

$$v_\pi(s) = \sum_{\mathsf{a} \in \mathcal{A}} \pi(\mathsf{a}|s) q_\pi(s,\mathsf{a})$$

Bellman Expectation Equation for Q^{π}

$$q_{\pi}(s, a) = \mathcal{R}_{s}^{a} + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^{a} v_{\pi}(s')$$

Bellman Expectation Equation for v_{π} (2)

$$v_{\pi}(s) = \sum_{a \in \mathcal{A}} \pi(a|s) \left(\mathcal{R}_{s}^{a} + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^{a} v_{\pi}(s')\right)$$

Bellman Expectation Equation for q_{π} (2)

$$q_{\pi}(s,a) \longleftrightarrow s,a$$

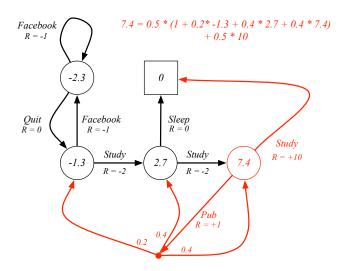

$$r$$

$$s'$$

$$q_{\pi}(s',a') \longleftrightarrow a'$$

$$q_{\pi}(s, a) = \mathcal{R}_{s}^{a} + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^{a} \sum_{a' \in \mathcal{A}} \pi(a'|s') q_{\pi}(s', a')$$

Example: Bellman Expectation Equation in Student MDP

Bellman Expectation Equation (Matrix Form)

The Bellman expectation equation can be expressed concisely using the induced MRP,

$$\mathbf{v}_{\pi} = \mathcal{R}^{\pi} + \gamma \mathcal{P}^{\pi} \mathbf{v}_{\pi}$$

with direct solution

$$v_{\pi} = (I - \gamma \mathcal{P}^{\pi})^{-1} \mathcal{R}^{\pi}$$

Optimal Value Functions

Optimal Value Function

Definition

The *optimal state-value function* $v_*(s)$ is the maximum value function over all policies

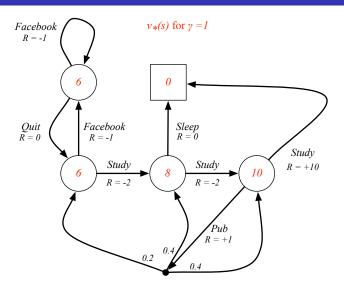

$$v_*(s) = \max_{\pi} v_{\pi}(s)$$

The optimal action-value function $q_*(s,a)$ is the maximum action-value function over all policies

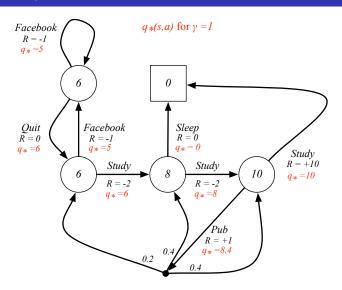

$$q_*(s,a) = \max_{\pi} q_{\pi}(s,a)$$

- The optimal value function specifies the best possible performance in the MDP.
- An MDP is "solved" when we know the optimal value fn.

Example: Optimal Value Function for Student MDP

Example: Optimal Action-Value Function for Student MDP

Optimal Policy

Define a partial ordering over policies

$$\pi \geq \pi'$$
 if $v_{\pi}(s) \geq v_{\pi'}(s), \forall s$

$\mathsf{Theorem}$

For any Markov Decision Process

- There exists an optimal policy π_* that is better than or equal to all other policies, $\pi_* \geq \pi, \forall \pi$
- All optimal policies achieve the optimal value function, $v_{\pi_*}(s) = v_*(s)$
- All optimal policies achieve the optimal action-value function, $q_{\pi_*}(s,a) = q_*(s,a)$

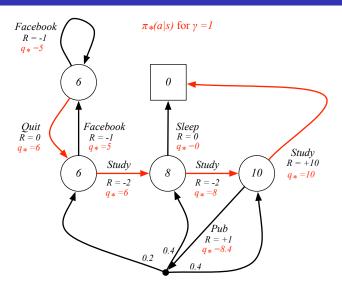

Finding an Optimal Policy

An optimal policy can be found by maximising over $q_*(s, a)$,

$$\pi_*(a|s) = \left\{ egin{array}{ll} 1 & ext{if } a = ext{argmax } q_*(s,a) \ 0 & ext{otherwise} \end{array}
ight.$$

- There is always a deterministic optimal policy for any MDP
- If we know $q_*(s, a)$, we immediately have the optimal policy

Example: Optimal Policy for Student MDP

Bellman Optimality Equation for v_*

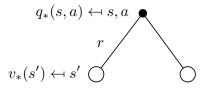

The optimal value functions are recursively related by the Bellman optimality equations:

$$v_*(s) \longleftrightarrow s$$

$$q_*(s,a) \longleftrightarrow a$$

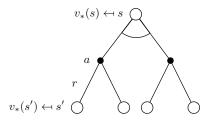

$$v_*(s) = \max_a q_*(s,a)$$

Bellman Optimality Equation for Q^*

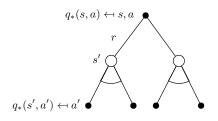

$$q_*(s, a) = \mathcal{R}_s^a + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a v_*(s')$$

Bellman Optimality Equation for V^* (2)

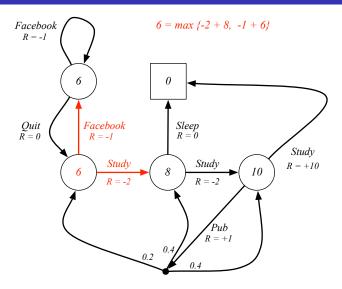

$$v_*(s) = \max_{a} \mathcal{R}_s^a + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a v_*(s')$$

Bellman Optimality Equation for Q^* (2)

$$q_*(s, a) = \mathcal{R}_s^a + \gamma \sum_{s' \in \mathcal{S}} \mathcal{P}_{ss'}^a \max_{a'} q_*(s', a')$$

Example: Bellman Optimality Equation in Student MDP

Solving the Bellman Optimality Equation

- Bellman Optimality Equation is non-linear
- No closed form solution (in general)
- Many iterative solution methods
 - Value Iteration
 - Policy Iteration
 - Q-learning
 - Sarsa

Extensions to MDPs

(no exam)

- Infinite and continuous MDPs
- Partially observable MDPs
- Undiscounted, average reward MDPs

Infinite MDPs

(no exam)

The following extensions are all possible:

- Countably infinite state and/or action spaces
 - Straightforward
- Continuous state and/or action spaces
 - Closed form for linear quadratic model (LQR)
- Continuous time
 - Requires partial differential equations
 - Hamilton-Jacobi-Bellman (HJB) equation
 - \blacksquare Limiting case of Bellman equation as time-step $\to 0$

POMDPs

(no exam)

A Partially Observable Markov Decision Process is an MDP with hidden states. It is a hidden Markov model with actions.

Definition

A *POMDP* is a tuple $\langle \mathcal{S}, \mathcal{A}, \mathcal{O}, \mathcal{P}, \mathcal{R}, \mathcal{Z}, \gamma \rangle$

- lacksquare $\mathcal S$ is a finite set of states
- lacksquare \mathcal{A} is a finite set of actions
- O is a finite set of observations
- $m{\mathcal{P}}$ is a state transition probability matrix,

$$\mathcal{P}_{ss'}^{a} = \mathbb{P}\left[S_{t+1} = s' \mid S_t = s, A_t = a\right]$$

- lacksquare \mathcal{R} is a reward function, $\mathcal{R}_s^a = \mathbb{E}\left[R_{t+1} \mid S_t = s, A_t = a\right]$
- **Z** is an observation function, $\mathcal{Z}_{c',a}^{a} = \mathbb{P}\left[O_{t+1} = o \mid S_{t+1} = s', A_t = a\right]$
- \bullet γ is a discount factor $\gamma \in [0, 1]$.

Belief States

(no exam)

Definition

A *history* H_t is a sequence of actions, observations and rewards,

$$H_t = A_0, O_1, R_1, ..., A_{t-1}, O_t, R_t$$

Definition

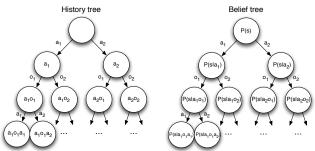

A belief state b(h) is a probability distribution over states, conditioned on the history h

$$b(h) = (\mathbb{P}[S_t = s^1 \mid H_t = h], ..., \mathbb{P}[S_t = s^n \mid H_t = h])$$

Reductions of POMDPs

(no exam)

- The history H_t satisfies the Markov property
- The belief state $b(H_t)$ satisfies the Markov property

- A POMDP can be reduced to an (infinite) history tree
- A POMDP can be reduced to an (infinite) belief state tree

Ergodic Markov Process

(no exam)

An ergodic Markov process is

- Recurrent: each state is visited an infinite number of times
- Aperiodic: each state is visited without any systematic period

Theorem

An ergodic Markov process has a limiting stationary distribution $d^{\pi}(s)$ with the property

$$d^{\pi}(s) = \sum_{s' \in \mathcal{S}} d^{\pi}(s') \mathcal{P}_{s's}$$

(no exam)

Definition

An MDP is ergodic if the Markov chain induced by any policy is ergodic.

For any policy π , an ergodic MDP has an average reward per time-step ρ^{π} that is independent of start state.

$$\rho^{\pi} = \lim_{T \to \infty} \frac{1}{T} \mathbb{E} \left[\sum_{t=1}^{T} R_t \right]$$

- The value function of an undiscounted, ergodic MDP can be expressed in terms of average reward.
- $\tilde{v}_{\pi}(s)$ is the extra reward due to starting from state s,

$$ilde{v}_{\pi}(s) = \mathbb{E}_{\pi}\left[\sum_{k=1}^{\infty}\left(R_{t+k} -
ho^{\pi}\right) \mid S_{t} = s\right]$$

There is a corresponding average reward Bellman equation,

$$egin{aligned} ilde{v}_{\pi}(s) &= \mathbb{E}_{\pi} \left[(R_{t+1} -
ho^{\pi}) + \sum_{k=1}^{\infty} (R_{t+k+1} -
ho^{\pi}) \mid S_{t} = s
ight] \ &= \mathbb{E}_{\pi} \left[(R_{t+1} -
ho^{\pi}) + ilde{v}_{\pi}(S_{t+1}) \mid S_{t} = s
ight] \end{aligned}$$
